Introduction

Complex noun phrases involving relative clauses (1) are standardly treated as instances of "strong island" structural configurations into which a filler-gap dependency (FGD) cannot be formed between the filler (those kinds of flowers) and the gap (3) (Ross, 1967, den Dikken & Szabolcsi, 2002). This constraint is widely assumed to be universal.

Unexpectedly, Swedish and the other Mainland Scandinavian languages allow relative clause extractions (RCEs) (2) (Engdahl & Ejerhed, 1982; Erteschik-Shir, 1979), thus presenting a challenge to the universality of island constraints.

Existing accounts for the Swedish data

• Discourse-organizational factors (Erteschik-Shir & Lapin, 1979)
• Island-avoidance of overt coref resolution (Cirque, 1989)
• Structural reanalysis during parsing (Kush et al., 2013)

Unfortunately, none of these accounts stands up under closer scrutiny (see Christensen & Nyvad, 2014; Engdahl, 1997; Heimat & Wiklund, 2015; Lindahl, 2015; Muller, 2015). Thus, what drives the apparent felicity of Swedish RCEs remains undetermined.

Approaching the question via processing

• No on-line processing data exists for Swedish.
• Not clear whether processing patterns track intuitive well-formedness.

First step:

• Look for basic differences in processing between Swedish RCEs and other FGDs at the embedded verb (nRCE) and the following PP region (nRCE) (see examples 3-4) where integration is presumed to occur, while controlling for the possible influence of non-structural factors (e.g., working memory), which might affect the processing of FGDs.

Second step:

• Two studies suggest that in acceptability judgments and in online processing, only non-islands should show any modulating effects from plausibility and working memory on any primary manipulation.
• Sprossne et al. (2012) found no evidence that acceptability-based island-effects show any modulating effect from individual differences in general processing resource capacity, as measured via two Working Memory Span (WM) tasks and grammaticality judgement data (cf. Hofmeister & Sag, 2010).
• Traxler and Pickering (1996) demonstrated via eye tracking that manipulations to the plausibility of a filler as a continuation of a verb only affected integration for non-island structures, with no differences being found for island structures.

If correct, the presence of an interaction between structural and non-structural factors on Swedish RCEs could then serve as a positive heuristic for non-island status. This would help to confirm that processing of such structures is in-line with their intuitive acceptability.

Research goals and predictions

Use eye-tracking to test whether:
• Swedish RCEs elicit processing costs similar to hot or illict long-distance FGDs at the embedded verb (nRCE) and the following PP region (nRCE)
• Any basic structural differences are mediated by non-structural factors (e.g., working memory, pragmatic fit, and working memory).

Possible outcomes:
• Swedish RCEs do not involve island structures, and thus a structural account is still needed.
• True variation exists in island constraints.
• Swedish RCEs, although intuitively acceptable will pattern more like island structures. Such a finding would distantly "deep variation" in the island constraints themselves (see Phillips, 2013).

Method

Eye-tracking While Reading (Eyelink 1000 tower mount)

Reverse Digit Span (DS) (adapted into Swedish from MacWhinney et al., 2001). Participants hear a series of digits (3- infinite set size) and then enter them on a computer keyboard in reverse.

Automated O-span task (OS) (adapted into Swedish from Unsworth, et al., 2010). Mouse-driven recall task. Participants complete three interleaved sets: math operation and letter recall, each set size (3-7 count). Total of 75 letters and 75 math problems.

Participants:

48 native Swedish speakers

Materials

Eighty-long distance FGD sentence items (constructed using the Korg corpus), each appearing in four structural variants (Structure) (3-6) and six distractor items rotated over four lists.

Eyetracking while reading experiment

(1) *Those kinds of flowers, I saw a man that sold [ ]
(2) Såna [blomster] såg jag en man som såg [ ] (Swedish)
Those kinds of flowers I saw a man that sold

Early measures:
• RCE and TCE show similar facilitation relative to nRCE in early measures (First Fixation and Gaze Duration) at the verb (Region 1). This similarity was also present in one early measure (Gaze Duration) at the PP (Region 2). In Region 1, RCE also showed additional facilitation against the pcRCE control as OS and Prag increased.

Late measures:
• For both late measures of processing in Region 1, and for Total Durations in Region 2, RCEs were processed with more ease than nRCEs, patterning more similarly to TCEs as both OS and Prag increased. In Region 1 Total Durations, nRCE also showed some facilitation against the pcRCE control as Prag increased, but this could just be reflective of a late repair mechanism.
• Interpretation: Swedish RCEs are processed more similarly to non-island TCEs during late stages of integration.

Summary:
• RCEs appear to be easier to process than nRCEs. Facilitation is dependent in part on non-structural factors (working memory span and pragmatic fit).
• Our study thus provides novel evidence that Swedish RCEs are not processed like syntactic islands, in line with offline intuitions.
