Objective
To analyse and present the outcome of longitudinal change in ADL function and cognition in patients treated with galantamine for two years.

Methods and Subjects
The Swedish Alzheimer Treatment Study (SATS) is an open, long-term, multicentre study in a routine clinical setting. Patients with the diagnosis of Alzheimer’s Disease received the cholinesterase inhibitor galantamine. The 122 patients were assessed with several functional and cognitive rating scales including IADL, PSMS, FAST, MMSE, and ADAS-cog at baseline and every 6 months for a total period of two years.

The expected rate of IADL decline in untreated patients has been calculated using a linear equation as presented by Green et al.[1, 2]:

\[ \Delta IADL = 10.124 - 0.332 \times IADL_{\text{baseline}} \]

The patients in cluster 1 are more cognitive impaired at baseline than the other group and have lower percentage of apoE4-carriers. No significant differences in gender, duration, age at investigation or mean dose of galantamine during the study was observed. The cluster 1 patients also decline significantly faster in the long-term outcome of PSMS score compared to the other group; IADL and FAST scales do not show this difference.

Conclusions
The instrumental ADL scale in the galantamine treated patients showed a faster decline of function than the PSMS and FAST scales, but significantly less than expected by using the mathematical model by Green et al.

Increasing strength in the linear correlation between the three ADL scales as well as cognition was observed during the two years of the study. Cluster analysis based on ADL scores at baseline, identified two subgroups: with different cognitive ability, dissimilar proportion of apoE4-carriers and rate of change in basic functional decline.

Results
After two years of galantamine treatment the total mean change from baseline in PSMS score was 4.3 ± 4.9 (mean ± SD points). Using the mathematical model by Green et al. patients in this study are expected to decline approximately 11.7 ± 3.3 points on IADL score after 2 years. The IADL changes from baseline show a strong linear relationship (0.009<p<0.01) with cognition at the 18 and 24 months assessments.

110 patients with complete items in the three ADL scales at baseline were analysed in a two-step cluster analysis. Two clusters (groups) were identified (p<0.000).

IADL - Instrumental activities of daily living scale (0 - 31)
PSMS - Physical Self-Maintenance Scale (0 - 30)
FAST - Functional assessment staging (0 - 16)
MMSE – Mini Mental State Examination (0 - 30)
ADAS-cog - Alzheimer’s Disease Assessment Scale-cognitive subscale (0 - 70)
