# Background

A novel non-invasive method for generation of pressure volume loops (PV-loops) using brachial blood pressure and cardiovascular magnetic resonance (CMR) imaging has recently been presented and validated (1).

The aim was to investigate if PV-loop variables could provide incremental diagnostic information beyond conventional measurements in patients with acute myocardial infarction (MI).

### Method

- 100 patients with ST-elevation MI and CMR 2-6 days after MI
- 75 healthy volunteers with CMR
- Non-invasive PV-loops were measured by volumetric CMR data and brachial sphygmomanometric pressure (1)
- Maximal elastance (Emax = contractility), stroke work and ventriculoarterial coupling (Ea/Emax) were measured from the PV-loops (see Figure 1 for examples)
- Infarct size was assessed by late gadolinium enhancement
- Myocardium at risk was assessed by contrast-enhanced steady state free precession

Figure 1. Example of PV-loops in patients with myocardial infarction.

Variables	Myocardial infarction	Healthy volunteers	P-value
Contractility, mmHg/mL	1.34±0.48	1.50±0.41	0.024
Ventricular arterial coupling	1.27±0.61	0.73±0.17	<0.001
Stroke work, J	0.96±0.32	1.38±0.32	<0.001
EDV, mL	166.5±34.0	174.3±32.9	0.131
EF, %	48.6±10.0	61.0±5.9	<0.001

**Table 1.** PV-loop variables in patients with myocardial infarction and healthy volunteers.

### Results

All PV-loop variables differed significantly in patients with acute myocardial infarction compared to healthy volunteers (**Table 1**). Furthermore, contractility, stroke work and ventriculoarterial coupling correlated to infarct size (Emax: r<sup>2</sup>=0.29, Ea/Emax: r<sup>2</sup>=0.41, stroke work: r<sup>2</sup>=0.25) and myocardium at risk (Emax: r<sup>2</sup>=0.25, Ea/Emax: r<sup>2</sup>=0.36, stroke work: r<sup>2</sup>=0.21) as shown in

Figure 2. Stroke work, contractility and ventriculoarterial coupling versus myocardium at risk (left column) and infarct size (right column).

## Conclusion

Non-invasive cardiovascular magnetic resonance derived PV-loop variables such as contractility, stroke work and ventriculoarterial coupling provide incremental diagnostic information beyond cardiac dimensions and ejection fraction early after acute myocardial infarction.
